PERMISSION TO USE

In presenting this thesis/dissertation in partial fulfillment of the requirements for a Postgraduate degree from the University of Saskatchewan, I agree that the Libraries of this University may make it freely available for inspection. I further agree that permission for copying of this thesis/dissertation in any manner, in whole or in part, for scholarly purposes may be granted by the professor or professors who supervised my thesis/dissertation work or, in their absence, by the Head of the Department or the Dean of the College in which my thesis work was done. It is understood that any copying or publication or use of this thesis/dissertation or parts thereof for financial gain shall not be allowed without my written permission. It is also understood that due recognition shall be given to me and to the University of Saskatchewan in any scholarly use which may be made of any material in my thesis/dissertation.

Requests for permission to copy or to make other uses of materials in this thesis/dissertation in whole or part should be addressed to:

Head of the Department of Psychology

Abstract

There are competing theories in the literature regarding the extent to which the translation of print to speech involves single or multiple routes. Regardless of the number of routes in a model, all models of reading must account for both sight vocabulary (SV) processing, which specializes in mapping whole-word representations, and phonetic decoding (PD) processing, which specializes in mapping sub-word representations. The purpose of the present work was to examine two hypotheses regarding the relationship between SV and PD: independence versus redundancy. Both behavioural and functional Magnetic Resonance Imaging (fMRI) experiments were conducted and the results supported the hypothesis that SV and PD are behaviourally and neurobiologically independent processes. Furthermore, in the interest of advancing all models of basic word recognition, the neurobiological representations of some of the sub-systems within SV and PD routes were explored and the contribution that particular brain regions make to the completion of naming particular stimuli was evaluated. Finally, basic and applied areas of research were integrated to demonstrate how diagnostic stimuli developed from basic reading research can inform us about impaired reading performance following traumatic brain injury.
Acknowledgements

Thank you to my supervisor, Dr. Ron Borowsky. Over the years, you have given me an insurmountable amount of your time and patience. Your confidence and encouragement has been essential to my achievements and success. I take with me a vast amount of knowledge, which I have learned from your professional disposition during lectures, talks, and conferences to your quirky character on fMRI nights that can only be understood by those who have been driven beyond exhaustion. You are a model supervisor that I hope to emulate and provide to my future students the same level of respect and consideration that you have shown me. Finally, and most importantly, thank you for your friendship.

I would like to thank my committee, Dr. Gordon Sarty, Dr. Lorin Elias and Dr. Jonathan Farthing. Your guidance and advice over the years has made my graduate experience exceptional and well-rounded given the eclectic nature of your professional and personal backgrounds and accomplishments.

Thank you to my husband Shea, my girls, Daelyn and Amaia, and my family for your continued understanding, support and encouragement. Without your love and acceptance none of this would have been possible.
